COSA CALLS FOR

COSA ENCOURAGES ALL HEALTH PROFESSIONALS INVOLVED IN THE CARE OF PEOPLE WITH CANCER TO:

1. **Discuss** the role of exercise in cancer recovery
2. **Recommend** their patients follow the exercise guidelines*
3. **Refer** their patients to a health professional who specialises in the prescription and delivery of exercise (i.e. accredited exercise physiologist or physiotherapist with experience in cancer care)

* A number of people with cancer (such as those coming to the end of life and with severe limitation) require highly specialised support and are not appropriate for general exercise advice. Clinical judgement should always be applied.
Exercise to be embedded as part of standard practice in cancer care and to be viewed as an adjunct therapy that helps counteract the adverse effects of cancer and its treatment.

All members of the multidisciplinary cancer team to promote physical activity^ and recommend people with cancer follow the exercise guidelines*

Optimal practice to offer referral to an accredited exercise physiologist or physiotherapist with experience in cancer care for an individualised exercise program.

Effective exercise prescriptions can be delivered in hospitals, cancer treatment centres, community and home-based settings.

^ Whilst COSA supports the benefits of physical activity (e.g. active gardening and incidental walking), this position statement focuses on providing an evidence based framework for structured exercise in cancer care.
COSA’S POSITION

- All people who have had a cancer diagnosis to avoid inactivity and return to normal daily activities as soon as possible following diagnosis (i.e. be as physically active as current abilities and conditions allow)
- All people who have had a cancer diagnosis* to participate in regular physical activity with the aim, as able, of reaching and maintaining:
  - at least 150 minutes of moderate-intensity or 75 minutes of vigorous-intensity aerobic exercise (e.g. walking, jogging, cycling, swimming) each week; and
  - two to three resistance exercise sessions (e.g. TheraBand, Pilates, lifting weights) each week involving moderate- to vigorous-intensity exercises targeting the major muscle groups
- Exercise recommendations to be tailored to the individual’s abilities noting that specific exercise programming adaptations may be required for people with cancer based on disease and treatment-related adverse effects, anticipated disease trajectory and their health status
- Effective exercise prescriptions can be delivered across a variety of settings including hospital, cancer treatment centre, community and home-based (i.e. self-managed).
- Accredited exercise physiologists or physiotherapists with experience in cancer care are the most appropriate health professionals to prescribe and deliver exercise programs to people with cancer**
- All health professionals involved in the care of people with cancer have an important role in promoting these recommendations

This document contains general principles only and should not be used as a substitute for individual exercise prescription. Consideration of exercise safety for an individual should be assessed by a health professional with knowledge of cancer, prior to exercise commencement.

* A number of people with cancer (such as those coming to the end of life and with severe limitation) require highly specialised support and are not appropriate for general exercise advice. Clinical judgement should always be applied.

** Services provided by accredited exercise physiologists and physiotherapists are eligible for subsidies through Medicare and private health insurers. An extensive number of exercise physiologists and physiotherapists are based in the community and can be located using online search functions of the respective accrediting bodies:
Physiotherapists – www.choose.physio/
The term physical activity applies to any movement produced by skeletal muscles that requires the body to exert energy. Exercise is structured physical activity for the purpose of conditioning the body to improve health and fitness. To maximise the therapeutic potential of exercise, well-established principles of training (including specificity, progression, overload, individualisation) should be applied and operationalised using the FITT formula – frequency (number of exercise sessions), intensity (how hard per session), time (session duration) and type (exercise modality) [1, 2].

Clinical research has established exercise as a safe and effective intervention to counteract many of the adverse physical and psychological effects of cancer and its treatment. To date, the strongest evidence exists for improving physical function (including aerobic fitness, muscular strength and functional ability), attenuating cancer-related fatigue, alleviating psychological distress and improving quality of life across multiple general health and cancer-specific domains [3-17]. Emerging evidence highlights that regular exercise before, during and/or following cancer treatment decreases the severity of other adverse side effects and is associated with reduced risk of developing new cancers and comorbid conditions such as cardiovascular disease, diabetes and osteoporosis [3, 4]. Furthermore, epidemiological research suggests that being physically active provides a protective effect against cancer recurrence, cancer-specific mortality and all-cause mortality for some types of cancer (research has predominantly focused on breast, colorectal and prostate cancers) [3, 18-27]. These findings have set the scene for a number of clinical trials, which are currently underway to rigorously evaluate the effects of exercise on cancer survival.

The convincing body of epidemiological and clinical trial evidence on the benefits of exercise has led to the endorsement of exercise guidelines for people with cancer by major organisations internationally [28-33]. These guidelines largely mirror guidelines for the general population (as outlined in the previous section). Despite this advice being widely disseminated by government and non-government cancer organisations, the majority of Australian’s with cancer do not meet these recommended targets [34-36]. Reports indicate that approximately 60-70% of people with cancer do not meet aerobic exercise guidelines and it is estimated that approximately 80-90% do not meet resistance exercise guidelines [34-36]. Thus, while many people with cancer have indicated a desire to participate in appropriately designed and supervised exercise programs [37-45], only a minority are engaging in sufficient levels of exercise.

This document outlines COSA’s position with respect to exercise recommendations [28-33], taking into account the strengths and limitations of the epidemiological and clinical trials evidence base.

Key Points:

• Being physically active and exercising regularly is important for the health, function, quality of life and potentially survival of people with cancer

• The majority of people with cancer do not meet exercise recommendations

• People with cancer express a desire to become and stay sufficiently active but need advice and support to do so

• To maximise safety and therapeutic effect, it is optimal for exercise to be prescribed and delivered under the direction of an accredited exercise physiologist or physiotherapist with experience in cancer care. The focus would be to transition to ongoing self managed exercise as able, and appropriate over time.
This Position Statement was initially endorsed by a meeting of COSA Council on 18 August 2017, and following revision and update, re-endorsed on 16 October 2020. It remains in effect for five years from the latter date during which time the Position Statement may be amended by action of COSA Council.

ENDORSED BY

Position statements produced by COSA are stand-alone documents, the content of which is not influenced by any other authority. COSA is pleased to have the support of the following endorsing organisations:

GLOSSARY OF EXERCISE TERMINOLOGY

Physical Activity: Any bodily movement produced by the contraction of skeletal muscles that results in a substantial increase in caloric requirements over resting energy expenditure.

Exercise: A type of physical activity consisting of planned, structured, and repetitive bodily movement for the purpose of improving and/or maintaining health and physical fitness.

Aerobic exercise: A form of exercise that predominately stresses the cardiovascular system; any exercise that uses large muscle groups, can be maintained continuously and is rhythmical in nature; examples include walking, jogging, cycling, swimming; also referred to as cardiovascular exercise or endurance exercise.

Resistance exercise: A form of exercise that predominately stresses the musculoskeletal system; any exercise that requires a muscle or a muscle group to work against external resistance; examples include squats, chair rises, chest press, push ups; also referred to as muscle strengthening exercise or weight training.

FITT principle: A method of prescribing exercise that includes specification of the frequency (i.e. number of exercise sessions), intensity (i.e. how hard/difficult the exercise is), time (i.e. duration of exercise) and type (i.e. exercise modality) of exercise to be performed. The exact composition of the FITT principle of exercise prescription should be revised according to the individual response, need, limitation and adaptations to exercise as well as evolution of the goals and objectives of the exercise program.

Exercise intensity: The level of exertion required when exercising (i.e. how hard/difficult the exercise is), based on the level of physiological stress required to complete the exercise.

Moderate intensity exercise: Exercise stimulus that requires patients to work at a level of exertion equivalent to 40-59% of heart rate reserve; exertion perceived as ‘somewhat hard’; e.g. brisk walking, cycling and/or swimming at a somewhat hard pace.

Vigorous intensity exercise: Exercise stimulus that requires patients to work at a level of exertion equivalent to 60-89% of heart rate reserve; exertion perceived as ‘hard to very hard’; e.g. running, cycling and/or swimming at a hard pace.

Specificity: A principle of exercise prescription that stipulates physiological adaptations are specific to the body system/s trained with exercise.

Overload: A principle of exercise prescription that stipulates exercise dosage must be increased for continued improvement; i.e. exercise below a minimum threshold does not sufficiently challenge the body to result in physiological adaptation.

Progression: A principle of exercise prescription that stipulates a gradual increase in exercise dosage is required for continued physiological adaptation; i.e. the dosage must increase to maintain overload.

Individualisation: A principle of exercise prescription that stipulates the customised application of exercise towards the physiological status of the patient.

Recovery: A principle of exercise prescription that stipulates time between exercise sessions is required in order to permit the necessary biological resynthesis to replace the required constituents of the body system/s stressed by exercise.

Exercise dosage: The overall level of exposure to exercise; based on a combination of the volume and intensity of exercise.

Exercise volume: The amount of exercise performed (i.e. how much exercise); based on a combination of the exercise duration and frequency.

ABOUT COSA

The Clinical Oncology Society of Australia (COSA) is the peak national body representing multidisciplinary health professionals whose work encompasses cancer control and care. COSA members are doctors, nurses, scientists and allied health professionals involved in the clinical care of people with cancer. COSA is affiliated with and provides medical and scientific advice to Cancer Council Australia.

COSA is the only organisation that provides a perspective on cancer control activity in Australia from those who deliver treatment and care services across all disciplines. The benefits of membership include discounted registration to COSA’s Annual Scientific Meeting, access to a range of education programs and workshops, Cancer in the News daily email and subscriptions to Cancer Forum and the Asia Pacific Journal of Clinical Oncology. Please visit our website at www.cosa.org.au for more information.

The COSA Exercise and Cancer Group focuses on enhancing supportive care practice and policy with the aim of improving outcomes for patients through affordable, accessible and effective exercise medicine.
